Direct and indirect detection

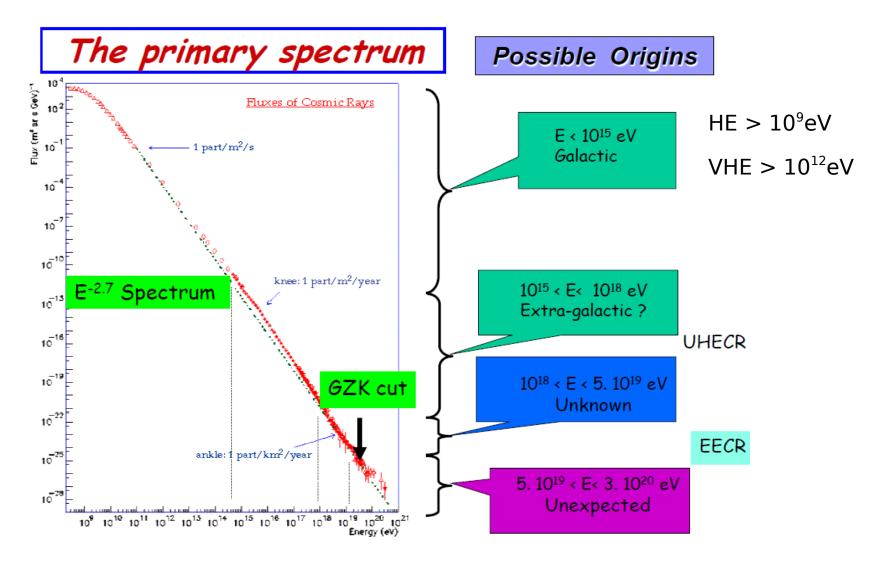

Charged Cosmic Ray Energy Spectrum

Tuxtla Gutierrez 27th of October 2016

More nomenclature and suggested origin

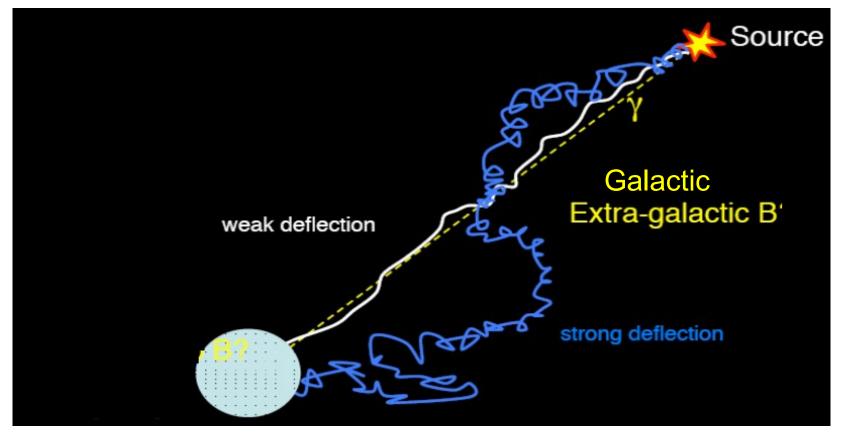

Omar Tibolla

Gamma-rays (and neutrinos) have one big advantage...

...they are not deflected by Galactic and extragalactic magnetic fields \rightarrow <u>direction</u>

Tuxtla Gutierrez 27th of October 2016

Primary Galactic cosmic-rays up to the so called "knee" at about 10¹⁵ eV, are accelerated in SNRs.

One expects about one supernova event every 30 - 50 years, and, in order to account for the energy density of CRs (about 1 eV/cm³) and the CRs confinement time deduced from spallation, the typical non-thermal energy release per supernova has to be about 10⁵⁰ ergs, which is about 10% of the total energy released.

(Ginzburg and Syrovatskii (1964), Soviet Astronomy, 8, 342)

This is in good agreement with the typical amount of energy predicted to be produced during the acceleration of relativistic particles in SNR shocks.

(Drury, Markiewicz and Völk (1989), A&A, 225, 179)

(Völk and Biermann (1988), ApJ, 333, L65)

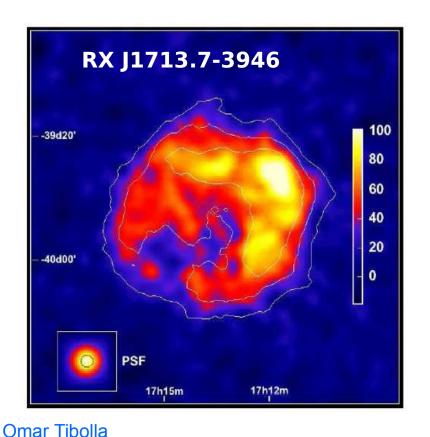

(Drury, Aharonian and Völk (1994), A&A, 287, 959)

Omar Tibolla

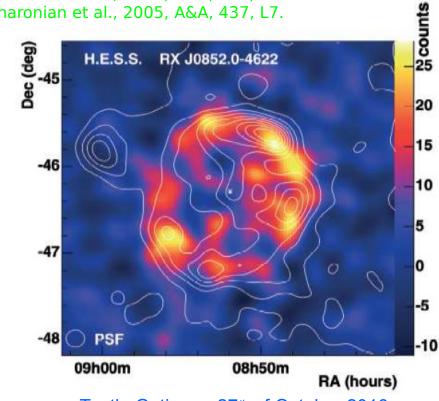

Tuxtla Gutierrez 27th of October 2016

The detection by the Imaging Atmospheric Cherenkov Telescopes (IACTs) of TeV gamma rays from supernova remnants (SNRs), spatially coincident with the sites of non-thermal X-ray emission, has strengthened the hypothesis of the "standard" picture of CR origin for up to the "knee".

Aharonian et al., 2006, A&A, 449, 223. Aharonian et al., 2005, A&A, 437, L7,

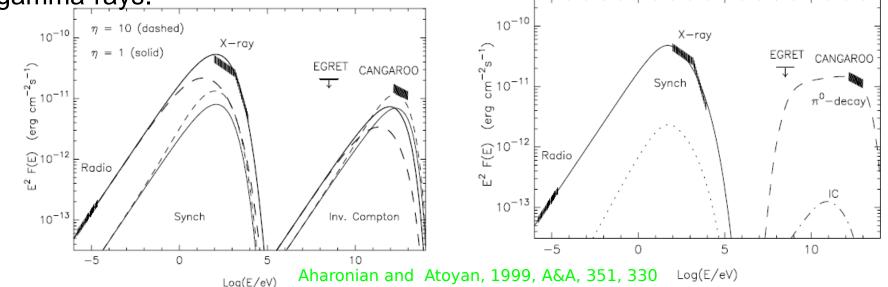

Tuxtla Gutierrez 27th of October 2016

The TeV gamma ray signal, can be explained in 2 ways:

- Inverse Compton scattering of relativistic electrons/positrons on background photons (CMB, infrared, X-rays, etc.)
- Neutral pion decay (p-p interaction)

And hadronic and leptonic model are basically indistinguishable at TeV gamma-rays.

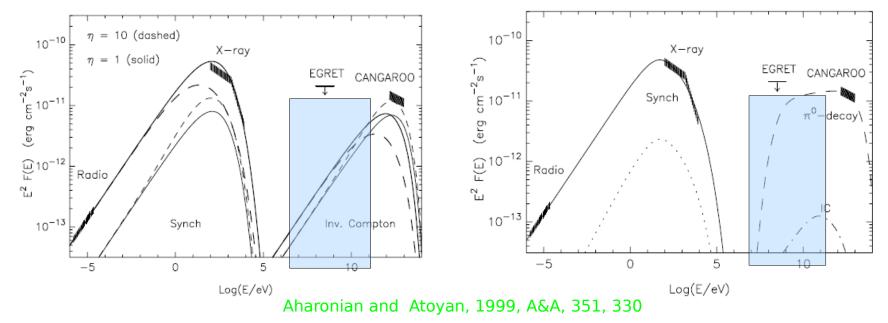

SNRs proved to be sources of cosmic ray electrons a decade ago, because of the radio and X-ray emissions detected, no compelling evidence for the acceleration of hadrons (>90% of CRs) in SNRs has been found. Omar Tibolla
Tuxtla Gutierrez 27th of October 2016

However..

Taking the same example...we see that the adjacent GeV gamma-ray band, we can finally prove or disprove it.

And it was indeed among the scientific purposes (GLAST Science Brochure 1996; http://glast.gsfc.nasa.gov) of Fermi-LAT, that was projected (also) to be a great observatory for SNRs (e.g. Tibolla 2007, MPLA, 22, pp. 1611-1619).

Fermi-LAT detected several SNRs (and SNR/MC interactions): references

A. A. Abdo et al. (including O. Tibolla), "FermiLAT Study of Gamma-ray Emission in the Direction of Supernova Remnant W49B", ApJ, 722, pp. 1303-1311 (2010).

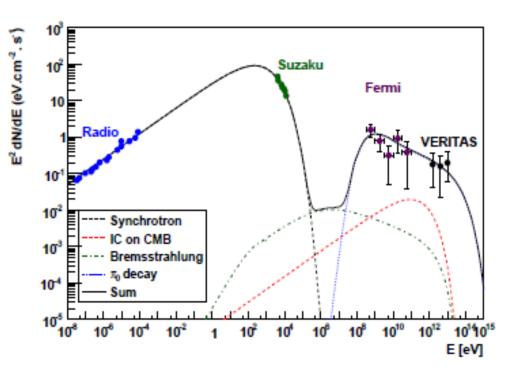

Among the Femi LAT SNRs sample, a very important discovery is represented by Tycho.

In the case of Tycho, leptonic models are basically disproved (!!!); i.e. Tycho represents the "smoking gun", the "hadronic fingerprint", i.e. the answer to a 60-100 years old question!

((Note: the TeV spectrum recently changed/has been updated, but the result did not change))

So everything would look solved and every question answered...BUT...

Tuxtla Gutierrez 27th of October 2016

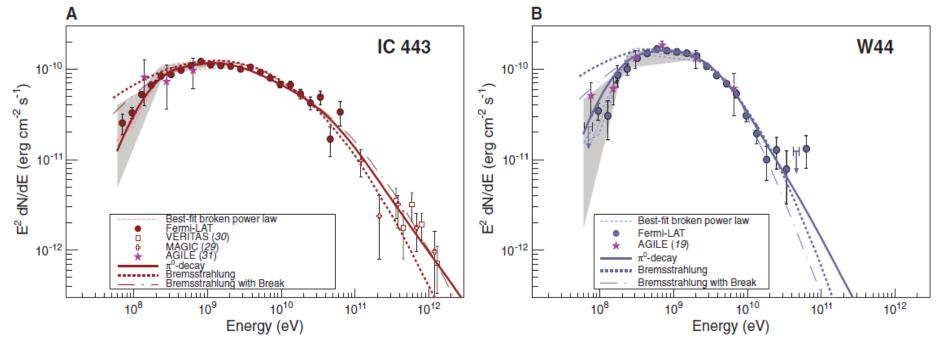

Note (Additional approach):

Additionally, we could detect hints of the neutral pion "shoulder" around 100 MeV (for IC 443 and W44): *M. Ackermann et al. (including O. Tibolla), Science, 339, pp. 807-811 (2013).*

...if these two example are less relevant than Tycho SNR since they deal with SNRs/MCs interacting systems...

This would seem to underline that everything is solved and every question answered...BUT...

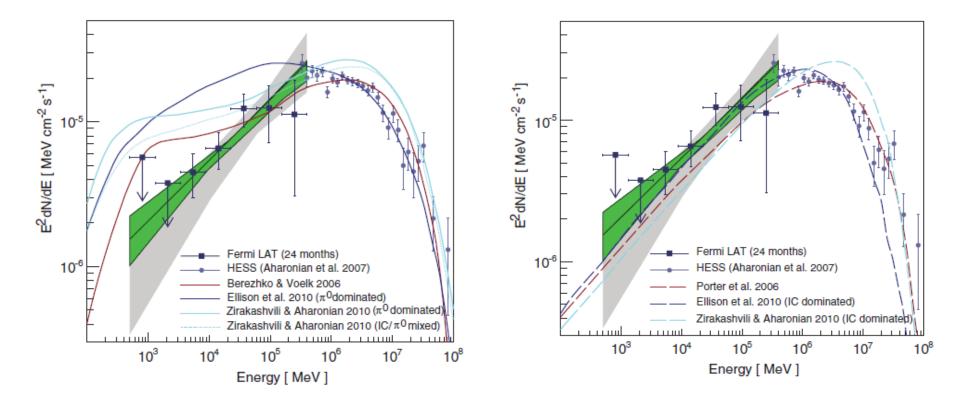

Omar Tibolla

...but

Some shell-type SNRs seem leptonic..

E.g. RX J1713.7-3946, one of the most promising targets and moreover one of the best threated by theoretical models...

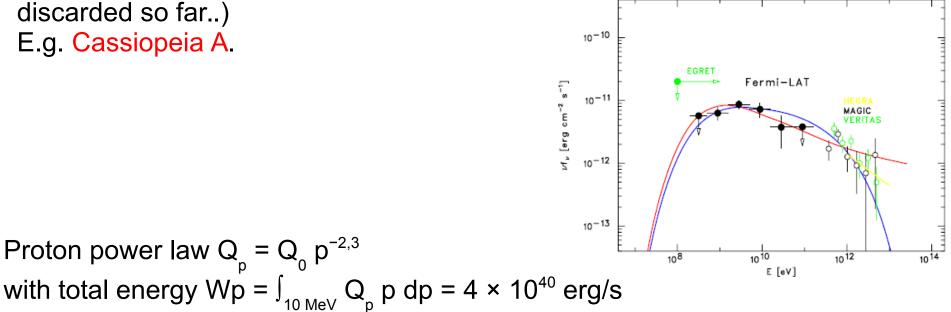

Tuxtla Gutierrez 27th of October 2016

...but (2)

And also among the one that look more likely hadronic (in most of the LAT SNRs, hadronic models are favored..but leptonic ones cannot be fully

Note that this would correspond to $\underline{\sim 2\%}$ of the SNR kinetic energy. (for more details O. Tibolla et al., arXiv:1109.3144)

...the <u>question</u> is still <u>open</u>...

Omar Tibolla

Basically two ways to proceed:

- 1- modify Standard Model(s).
- e.g. J. Vink models on Cas A.

e.g. what if the local density of CRs (i.e. inside the "local bubble") is different or very different from the CRs density outside the local bubble? This would change the game...

2- searching alternative sources which might help us in closing the gap (if any).

E.g. (let's advertise CRBTSM 2014 book and CRBTSM 2016 once more) binary systems, protostellar jets, Galactic center, Pulsar and PWNe...but extragalactic sources (GRBs and AGNs) play a role as well.

...I think we should actually do both...

In order to close possible gaps, people search for other possibilities... Looking the high energy sky (i.e. the "non-thermal sky"), the dominant population is not represented by shell-type SNRs...

Among the known sources, **Pulsar Wind Nebulae (PWNe)** is the most numerous. And indeed it was proposed that at the termination shock of the Pulsar Wind, also hadrons could be accelerated as well as leptons (e.g. Bednarek & Protheroe 1997, PRL, 79, 2616 ; Atoyan & Aharonian 1996, MNRAS, 278, 525 ; Cheng et al. 1990, J. Phys. G, 16, 1115 ; Bednarek & Bartosik 2003, A&A, 405, 689).

But the most numerous population in absolute terms is represented by <u>Unidentified sources</u>. In fact almost 50% of the TeV Galactic sources are still unidentified; at GeV energies, 67% of EGRET sources were unidentified and also with the newer generation of gamma-ray satellites we have the same result: in fact, at low Galactic latitudes (b < 10 deg), 62% of the Fermi LAT detected sources have no formal counterpart.

<u>Hence understanding the high energy unidentified sources could be a crucial</u> <u>brick in solving the whole riddle of Cosmic Rays origin</u>. And the correlation with PWNe could be very close, at least for the so called "dark sources".

Gamma Ray Astronomy. How??

E.g. IR are stopped by CO_2 and H_2O , UV are stopped by O_3 , O_2 , N_3 , and so

On... Omar Tibolla

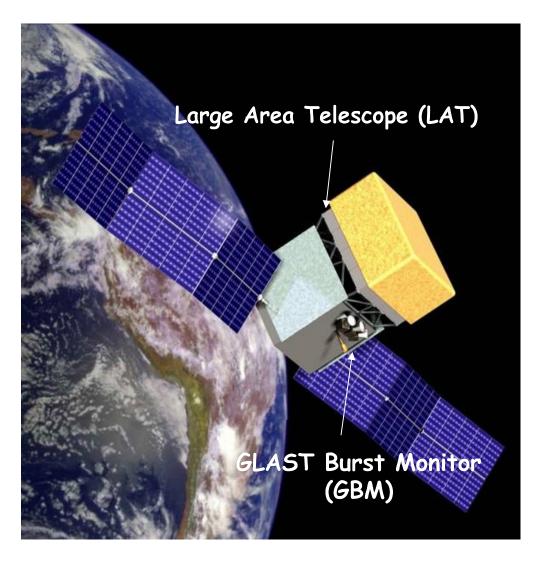

So...

Omar Tibolla

Tuxtla Gutierrez 27th of October 2016

Example: Fermi

Gamma-ray Large Area Space Telescope

- -France
- -Germany
- -Italy
- -Japan
- -Sweden
- -USA

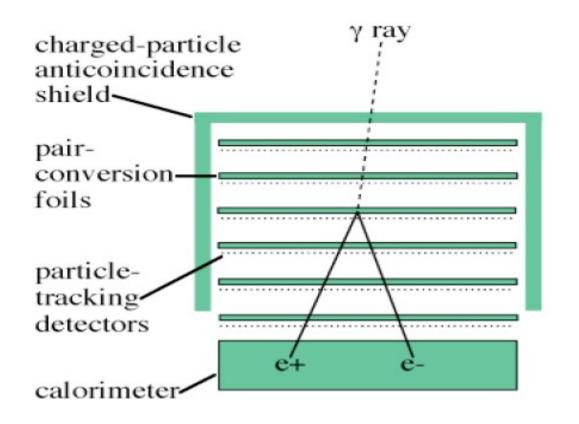

Energy Range 10 keV-300 GeV.

Imaging gamma-ray telescope (LAT)

- a second instrument to study Gamma Ray Bursts (**GBM**).

Pair conversion telescope

The main instrument is the Large Area Telescope (LAT): pair conversion telescope

Anticoincidence Shield (ACD) made of plastic scintillator (Bicron-408) sensitive to charged; ACD is segmented in order to avoid the self veto from Calorimeter backsplash, that caused 50% of loss in Aeff in EGRET, and also for micrometeorites.

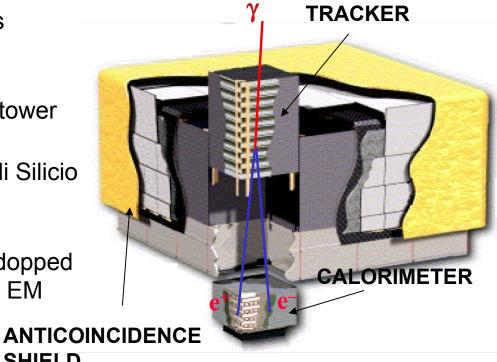

SHIELD

ACD contains 16 towers and each tower is divided in 2 parts:

- the **TRACKER** (**TKR**): 18 layers in each tower - Tungsten converter (1.08 χ_0)

-2 SSD ortogonal of Silicon microstrips di Silicio to detect electromagnetic "shower".

- the **CALORIMETER** (CAL): Csl cristals dopped by Tallium; so the energy deposited by the EM shower is converted in light signal.

Omar Tibolla

What are the advantages of using IACTs instead of satellites?

<u>Advantages</u>:

- provides a large detection area (needed at VHE energies)
- good sensitivity
- you could achieve quite large field of view
- good angular resolution
- good energy reconstruction
- built from proven technology

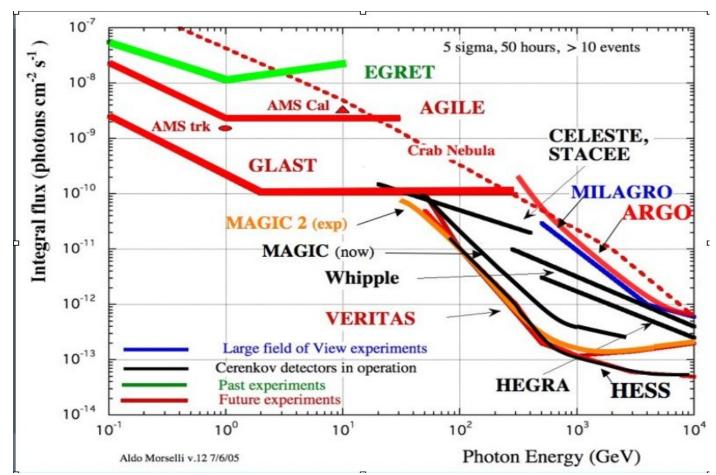

Disadvantages:

- indirect approach
- large background
- limited duty cycle
- small field of view (if compared to satellites)

Why Cherenkov Telescopes? (2)

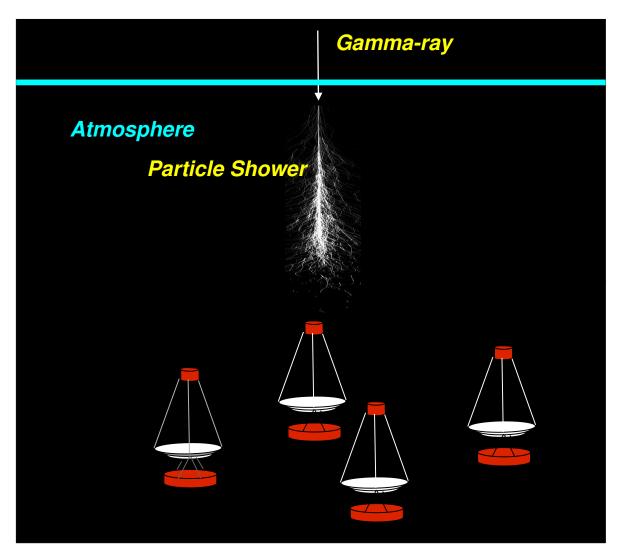

IACTs and satellites are complementary:

Tuxtla Gutierrez 27th of October 2016

Detection principle

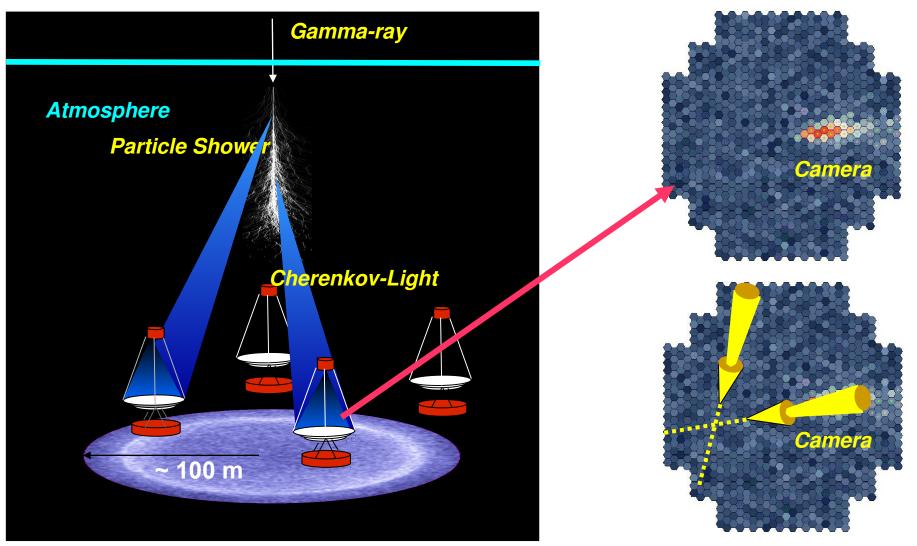

Tuxtla Gutierrez 27th of October 2016

Omar Tibolla

Detection principle: stereo approach

The approach described here is the so called "<u>stereo approach</u>", used by H.E.S.S. (and by VERITAS), and it has 2 important advantages:

- an easy and precise direction reconstruction.
- an improved background rejection (especially for muons)

However there is another approach (used by MAGIC) in which the <u>collecting</u> <u>area</u> is much <u>bigger</u>, in order to have much lower energy thresholds.

In order to have the advantages of both methods:

 $\mathsf{MAGIC} \to \mathsf{MAGIC} \ \mathrm{II}$

 $H.E.S.S. \rightarrow H.E.S.S. II$

(if you are interested, I have a lot of backup slides on H.E.S.S. and on MAGIC)

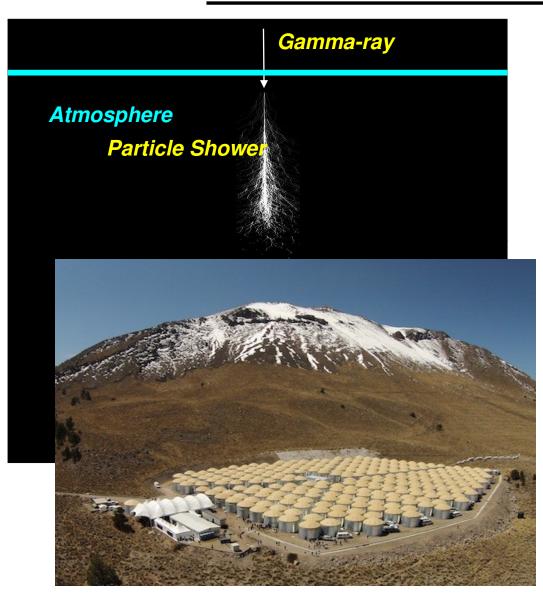

...and the next step for both collaborations (together with other experiments, such as FACT and ASTRI) is the:

Cherenkov Telescope Array (<u>CTA</u>).

Omar Tibolla

Water Cherenkov - HAWC

300 Water Cherenkov Detectors, (covering an area of four football fields)

HAWC: High Altitude Water Cherenkov Observatory

2 main advantages (if compared with IACTs):

- full-sky instrument
- no limited duty cycle

H.E.S.S. Survey

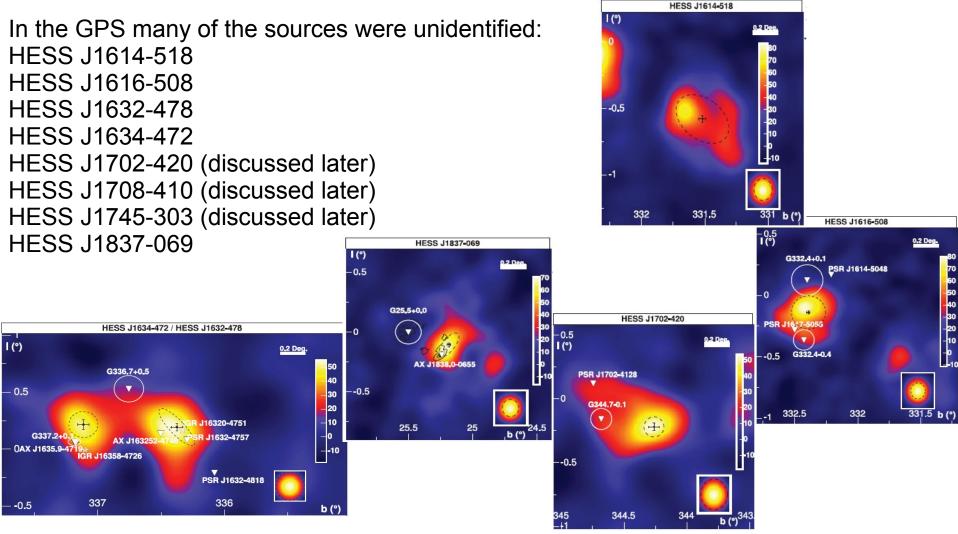

With the famous H.E.S.S. Survey (Aharonian et al., ApJ (2006) 636, 777-797) of 2004/2005, many new TeV gamma-ray sources have been discovered.

Omar Tibolla

Unidentified sources in the GPS

Tuxtla Gutierrez 27th of October 2016

H.E.S.S. Survey extension and VERITAS survey + HAWC

In the meaning while H.E.S.S., in 2006-2015, extended the successful VHE Galactic survey of 2004/2005, discovering a number of new sources, many of which are unidentified.

VERITAS in 2009/2015 started the scan of the northern part of the Galactic Plane.

In total (MAGIC + H.E.S.S. + VERITAS)

~120 Galactic sources discovered so far (and 50-60 extragalactic)

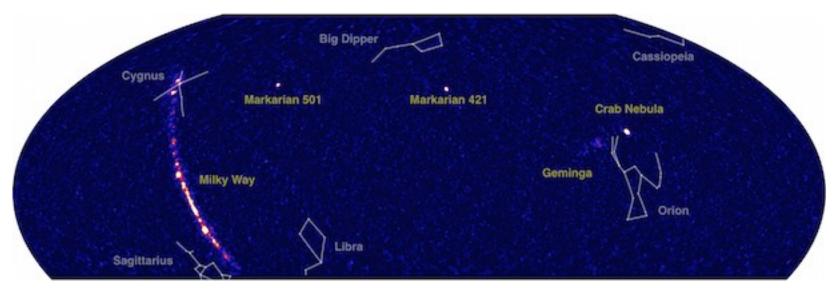

And additionally the "water Cherenkov technique" is reaching, with the HAWC (High Altitude Water Cherenkov) experiment, sensitivities comparable to IACTs ones (reaching higher energies)...

Water Cherenkov experiments have the advantage to be "full sky" experiments, so the number of sources is going to increase.

...in fact...

HAWC (HAWC-300) in 1 year data sees this (the paper will be published very soon):

(Sky map of Very High Eenergy gamma-rays observed by HAWC, taken from the recent press release)

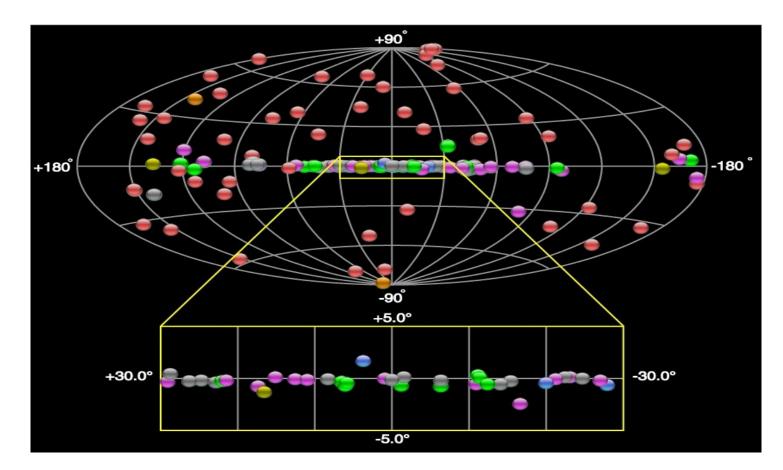

Most of the sources seem to confirm IACTs discoveries, but there seem to be some surprises/discoveries as well...

...and this is only the beginning of HAWC story...

Omar Tibolla

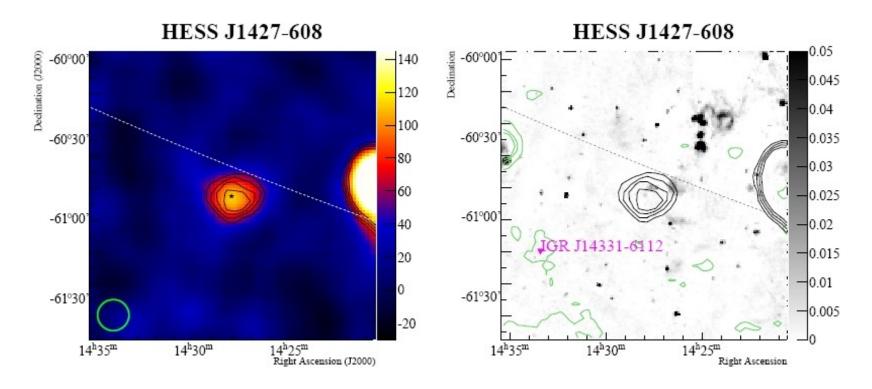

How many sources are unidentified?

~50% of the H.E.S.S. Galactic sources are still unidentified... (e.g. *Tam, Wagner, Tibolla and Chaves, A&A, 518, id.A8 (2010)*, even if GeV-TeV...) Omar Tibolla Tuxtla Gutierrez 27th of October 2016

HESS J1427-608

1° away from G313.2+0.3(hard X-ray and GeV γ -ray source in the Kookaburra region). 5.6 σ in 21 hours of observation.

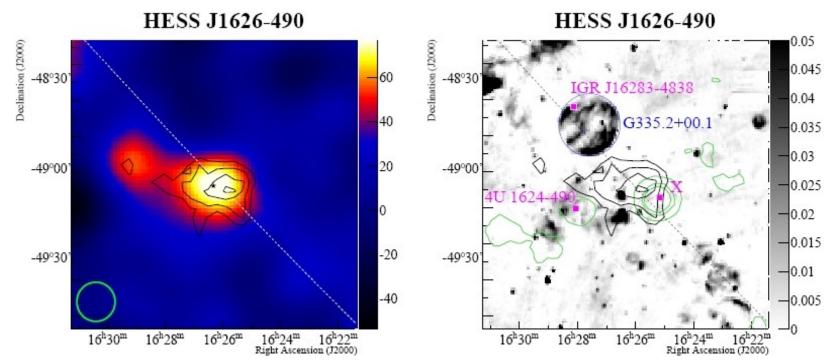

Spectrum fits well with a PL with index \sim 2.2.

In the right panel Radio (Molonglo survey) data and X-ray (RASS) contours in green.

Omar Tibolla

HESS J1626-490

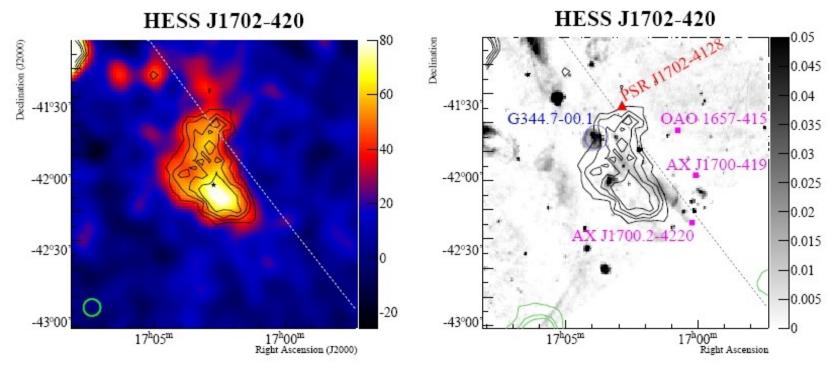

6 σ in 8 hours of observation.

Spectrum fits well with a PL with index ~2.2.

Labeled with an "X" in the right panel, the unidentified X-ray source *1RXS J162504-490918*, possible counterpart.

HESS J1702-420

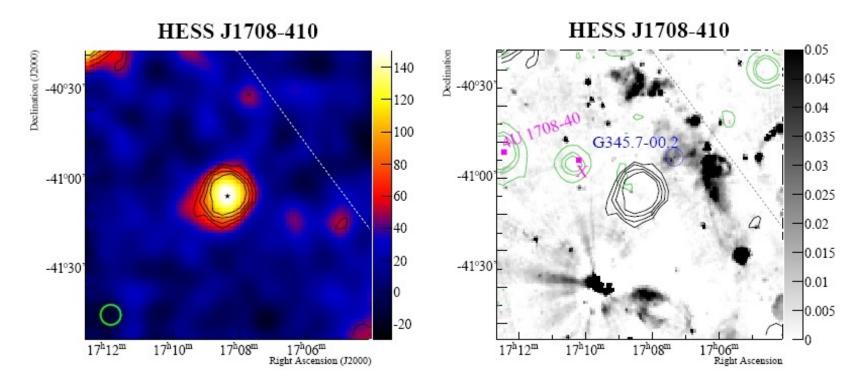

10.6 σ in 7 hours of observation.

Spectrum fits well with a PL with index ~2.1. PSR J1702-4128 (spin-down luminosity $1.3 \cdot 10^{34}$ erg/s kpc²) provides enough spin-down energy loss to produce the observed emission. Offset PWN? There are also a SNR (small in angular size and distant) and 3 XRB.

Omar Tibolla

HESS J1708-410

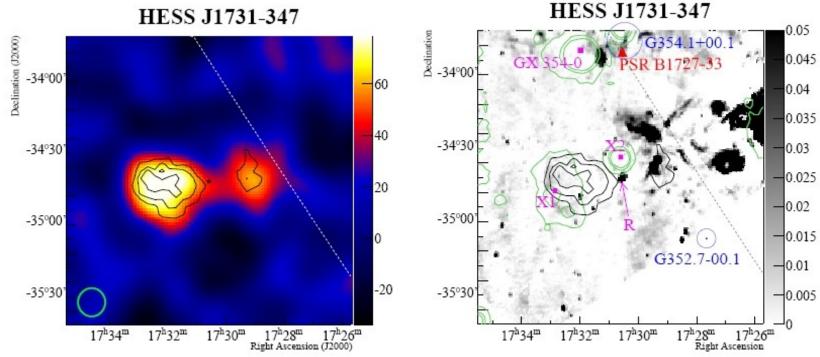

10.3 σ in 45 hours of observation.

Spectrum fits well with a PL with index ~2.5.

In the FoV: 1RXS J171011.5-405356, the SNR G345.7-00.2 and the XRB 4U 1708-40; no plausible counterparts.

HESS J1731-347

8.3 σ in 11 hours of observation.

Spectrum fits well with a PL with index ~2.3.

X1 is 1RXS J173251.1-344728, R is the radio point source 173028-344144 and X2 is the bright 1RXS J173030.3-343219.

HESS J1731-347 is the first SNR discovery triggered by TeV gamma-rays obs.

Omar Tibolla

HESS J1841-055

10.7 σ in 10 hours of observation.

Spectrum fits well with a PL with index ~2.4.

2 SNRs: Kes 73 (G027.4+00.0) and G26.6-0.1; 3 Pulsars: PSR J1841-0524 (spin-down luminosity $4.4 \cdot 10^{33}$ erg/s kpc²), PSR J1838-0549 (spin-down luminosity $4.7 \cdot 10^{33}$ erg/s kpc²) and PSR J1837-0604 (spin-down luminosity $5.2 \cdot 10^{34}$ erg/s kpc²); and AX J1841.0-0586 (a possible XRB).

HESS J1857+026 and HESS J1858+020

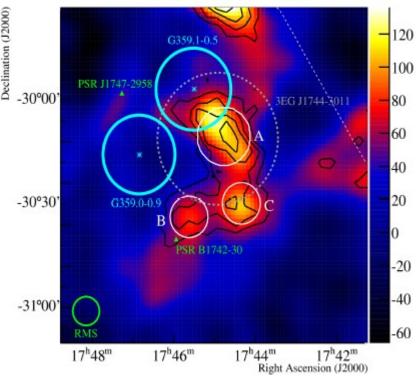

HESS J1857+026 (recently an identification with a PWN has been proposed): 10.2 σ in 15 hours of observation.

Spectrum fits well with a PL with index ~2.4.

HESS J1858+020 (recently an identification with a SNR has been proposed): 7.4 σ in 23 hours of observation. Spectrum fits well with a PL with index ~2.2. (X is 1RXS J185608+0218)

HESS J1745-303 (Galactic Center region)

HESS J1745-303

Newer observation has been performed on HESS J1745-303 and the results are published in F.Aharonian et al. *A&A*, 483 (2008) 509.

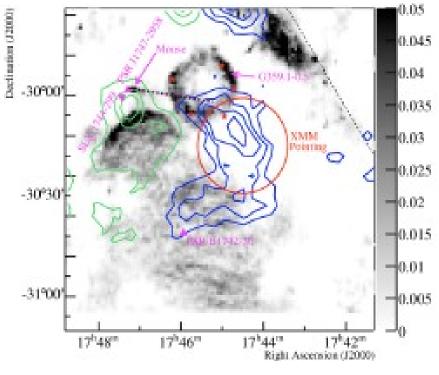

HESS J1745-303 is rather bright (12 σ in 79 hours of observation) and shows a complex morphology: it can be divided in 3 parts that show a slightly different spectral behavior:

- The spectral index for the full source is \sim 2.7;

- for part A is ~2.7
- for part B is ~2.9
- for part C is ~2.9

What is HESS J1745-303?

Radio (Monlonglo) and X-ray (ROSAT)

HESS J1745-303 is a very interesting TeV source, since it is one of the few TeV sources, spatially coincident with a source of the Third EGRET Catalog: 3EG 1744-3011.

The hot spot A seems to be correlated with the SNR G359.1-0.5 and Molecular Clouds (T.Dame et al. *ApJ*, *547* (2001) 792).

Other possible counterpart could be: - PSR B1742-30 (spin-down luminosity 2 · 10³³ erg/s kpc²) - PSR J1747-2958 (spin-down luminosity 4 · 10³⁵ erg/s kpc²) - the ultra compact XRB SLX 1744-300.

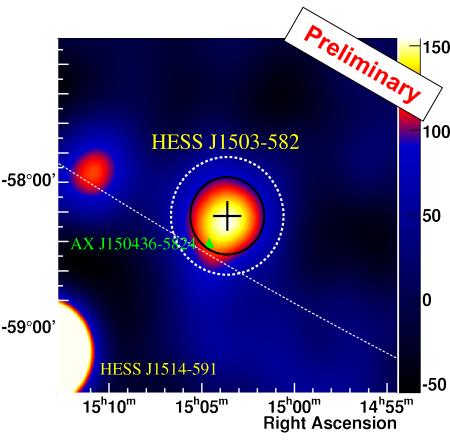

HESS J1503-582

HESS J1503-582: it does not have any of the typical counterparts (SNRs, PWNe, etc.), but it appears to be associate with a FVW (HI 21cm lines structures visible at velocities that deviate from Galactic rotation curve. (dynamical phenomena? E.g. fast moving of HI shells and filaments associated with old SNRs)

HESS J1503-582 shows significance of 6 σ in 24 hours of effective exposure. The spectrum can be fit well by a power law with index Γ = 2.4± 0.4_{stat} ± 0.2_{syst} with a flux above 1 TeV of 6 x 10⁻¹² cm⁻² s⁻¹ (~6 % of the Crab flux).

Note: the FVW hypothesis seems to be in contradiction with more recent VERITAS observations (ICRC 2009).

Tuxtla Gutierrez 27th of October 2016

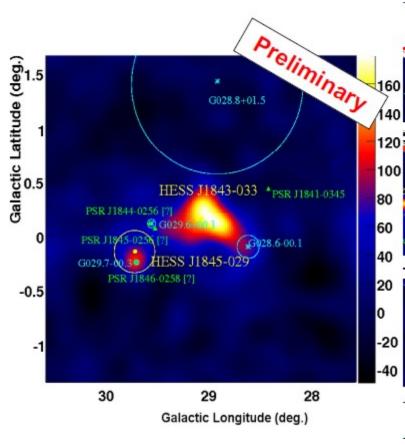

HESS J1843-033

HESS J1843-033 is one of the two brightest sources of the survey extension (9-10% of Crab)! Note: the map shown here is not updated (sorry, but the new results are not public yet).

Close to Kes 75. Several object close by, e.g.: - AX J1843.8-0352 (G28.60.1) is a SNR with a peculiar morphology: Chandra, that discovered a new source within it: CXO J184357-035441, that exhibits a thin thermal spectrum and a jet-like tail. - AX J1845.0-0258 is another very unclear object: it has been considered as an Anomalous X-ray Pulsar (AXP). Recently Chandra observed in that zone of the sky only one bright source: CXO J184454.6-025653 that is almost 13 times fainter than AX J1845.0-0258.

- A bright Fermi source..

However, the emission peak is not well studied in MWL; I got accepted two XMM-Newton proposals: ID 05563102, lost; ID 06549601 in the AO9 Omar Tibolla

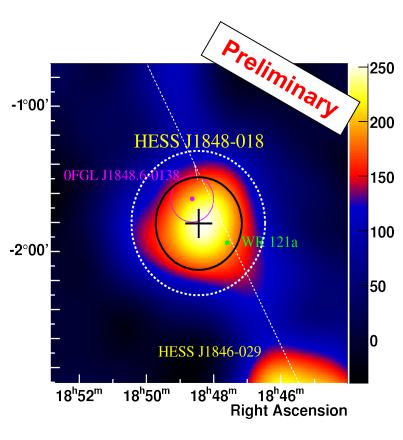

HESS J1848-018

HESS J1848-018: is still without counterparts, but it is slightly offset from the SFR W 43 (suggesting a possible association),which hosts a giant HII region (G30.8–0.2), a giant molecular cloud, and the Wolf- Rayet (WR) star WR 121a in the central stellar cluster.

If HESS J1848–018 is indeed associated with W 43, it would be only the second known case, after Westerlund 2 (or third, Westerlund 1), of VHE gamma-ray emission associated with a SFR.

The coincidence with the BSL Fermi source OFGL J1848.6-0138 is underlined.

The energy spectrum is well fit by a power law with index $\Gamma = 2.8 \pm 0.2_{stat} \pm 0.2_{syst}$ and integrated flux above 1 TeV of ~2 x 10⁻¹² erg cm⁻² s⁻¹, corresponding to ~2% that of the Crab nebula. Omar Tibolla

- Introduction to Cosmic Rays and "standard picture" of their origin.

- Detection techniques (GeV-TeV)
- What are Galactic unidentified sources?

Examples, "let's <u>go to unids zoo":</u> - HESS J1507-622 + ancient PWN - HESS J1741-302

- "Conclusions"

(+~100 backup slides)

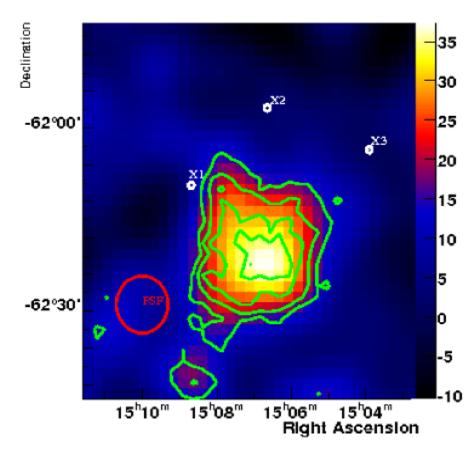

HESS J1507-622

Unique unidentified source:

- ~3.5 degrees offset from the Galactic plane!
- Very bright (~8% of the Crab). 9.3 σ of peak significance in 9.7 hours. Slightly extended (~0.16 degrees).

NO plausible counterparts at any wavelength.

Given the brightness and the offset from the Galactic plane, it is really surprising to not find any counterpart in X-rays!

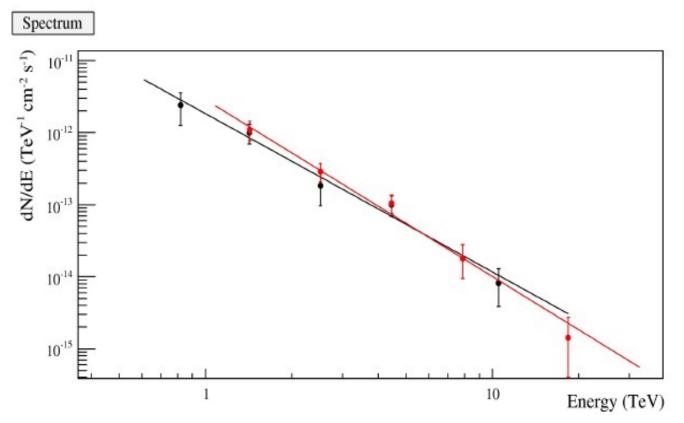

(X indicates the position of three faint RASS (Voges et al. 2000) sources: X1 indicates 1RXS J150841.2-621006, X2 indicates 1RXS J150639.1-615704 and X3 indicates 1RXS J150354.7-620408)

Omar Tibolla

Tuxtla Gutierrez 27th of October 2016

HESS J1507-622: spectra

The spectrum evaluated with *standard cuts* (i.e. lower energy threshold) and with *hard cuts* (i.e. better gamma-hadron separation). Compatible results;

- spectral index Γ = 2.24 <u>+</u> 0.36 Γ = 2.49 <u>+</u> 0.38
- flux (> 1 TeV): $(1.5 \pm 0.7) 10^{-12} \text{ cm}^{-2} \text{ s}^{-1}$; $(2.1 \pm 1.0) 10^{-12} \text{ cm}^{-2} \text{ s}^{-1}$

Omar Tibolla

Counterparts: IR and Radio

No plausible counterparts found in 1507 region!

At IR and Radio wavelengths:

- no Southern Galactic Plane Survey and Spitzer GLIMPSE coverage.

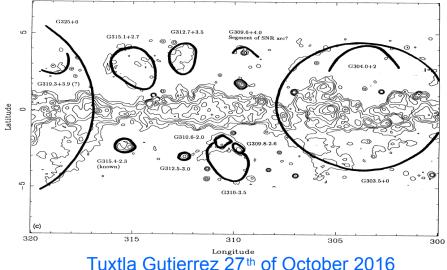

- covered by Midcourse Space Experiment (MSX) and by MOLONGLO Galactic plane survey, but without evidencing any plausible counterparts.

- it is located on a radio filament at 2.4 GHz (Duncan et al. 1995).

- it lies near the edge of a very large CO molecular cloud (5 deg x 2 deg) (Dame catalog).

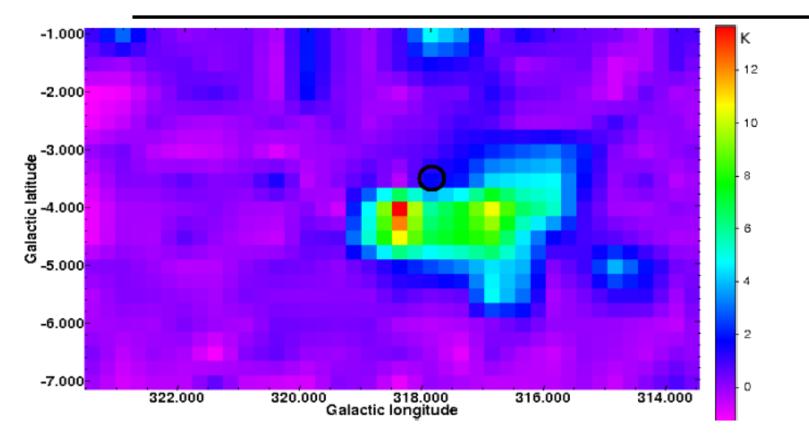

315

HESS J1507-622 overlapped into the 2.4 GHz Radio map and Duncan et al. interpretation

more on CO MCs

In the complete CO survey (Dame et al. 2001), the H.E.S.S. source lies near the edge of a large ($\sim 5 \text{ deg} \times \sim 2 \text{ deg}$) nearby CO molecular cloud, and the peak velocity of this cloud, around -5 km/s, would most likely place it quite near at a distance of $\sim 400 \text{ pc}$. The substantial difference in extension and, in the case of the CO molecular cloud, the offset of $\sim 1 \text{ deg}$ from the HESS source centroid, suggest no obvious scenario for an association. <u>Tuxtla Gutierrez 27th of October 2016</u>

Counterparts and MWL: X-rays

At X-rays (surprising to <u>not</u> find <u>any X-ray counterpart</u>, since we have here ~1 order of magnitude less absorption than in the Galactic plane) :

- <u>ROSAT</u> : no counterparts. 3 near point sources (see slide 49) (in the case that one of them could be discovered to be a PSR, one can imagine an offset PWN scenario).

- <u>XMM-Newton</u> : I got XMM-Newton observations (*Proposal ID #05563102 - AO 7*), but very severely affected by soft proton flare! Detected one point source in the middle of HESS J1507-622 (associated with a star). Re-observation has been obtained (*Proposal ID #06516201 - AO 9*): 35 ks.

- <u>Chandra</u> : I got Chandra observations (*Proposal ID #10400599 – AO 10*), no plausible counterpart, but an extended source has been discovered nearby.

- Accepted deep (80 ks) <u>Suzaku</u> campaign (priority C), and last year we got 80 ks + 40 ks observations.

(More details in Tibolla, Kaufmann and Kosack 2014, A&A, 567, id.A74)

Omar Tibolla

Chandra observations:

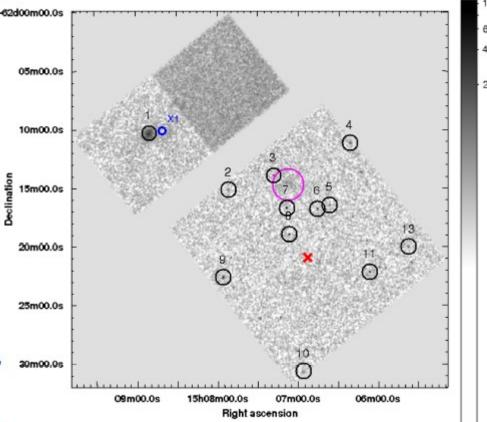

the situation is even more complicated

Using *vtpdetect* (confirmed by *wavdetect*) we find a faint extended source that escaped the source *celldetect* but is detected (116 counts over a level of background of 32 counts): 20-25 arcsec.

Much smaller angular size than the VHE source, so an association is not obvious with current data, although the possibility remains that it is a bright part of a larger, weaker source.

But for pulsars older than ~ 1000 years the VHE PWNe are typically 100-1000 times larger than the sizes of the X-ray PWNe (factor 2 for some younger PWNe, like the Crab).

However, in the case of HESS J1507-622, we see no PSR...

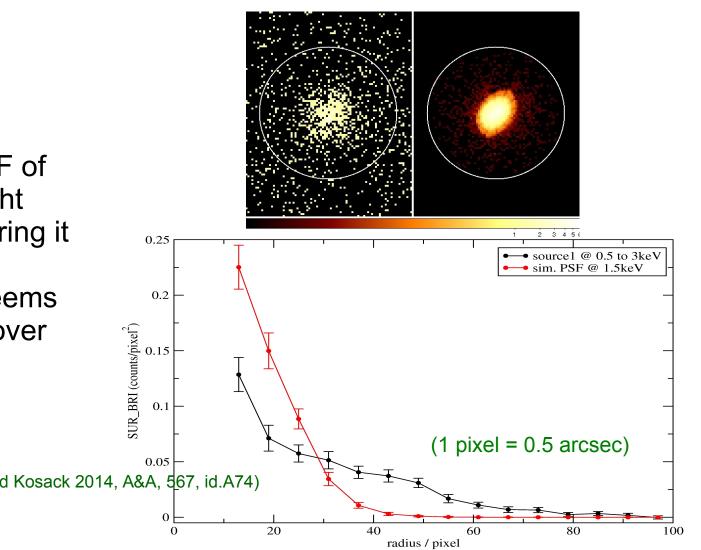

(More details in spare slides)

Source 1 extended?

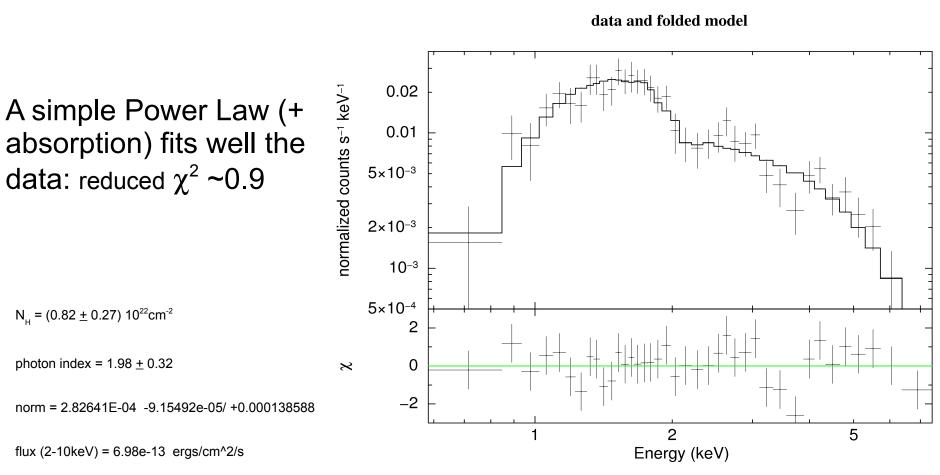

Simulating the PSF of the instrument (right panel) and comparing it with source 1 (left panel, source 1 seems slightly extended over the PSF of the instrument.

(Tibolla, Kaufmann and Kosack 2014, A&A, 567, id.A74)

error range (5.533e-13 - 7.582e-13)

Source 1 spectrum (2)

data and folded model

But also a simple thermal plasma fits as well. reduced $\chi^2 \sim 0.9$

Now we have another unidentified source in Radio and X-rays.

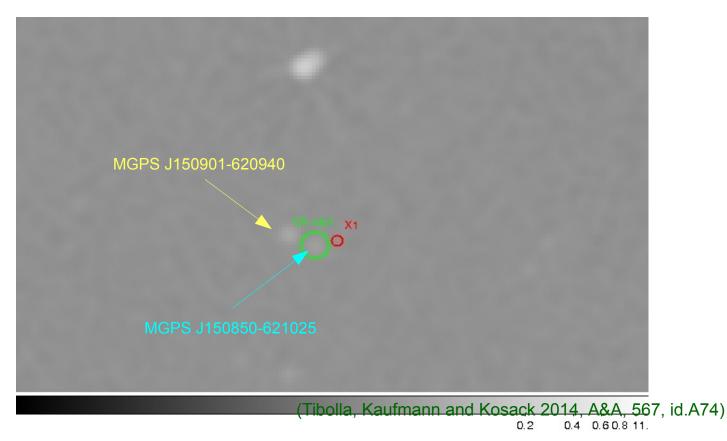

In any case, this newly discovered source does not seem to be a good counterpart candidate for HESS J1507-622.

Omar Tibolla

Note: MOLONGLO view of src1/X1

Src 1 is also coincident with MGPS J150850-621025 (62" times 50.4")(and close to MGPS J150901-620940: 51" times 50.6"). Overlapped src 1 (40" radius) and X1 (17" positional error).

Omar Tibolla

HESS J1507-622 doesn't show so far any obvious counterpart and its nature is still unclear. Both hadronic and leptonic scenarios are still under investigation.

- The offset from the galactic plane (low density..) would suggest a <u>leptonic</u> <u>scenario</u>. A PWN powered by an old PSR could be a possible explanation for this source (in this case a small distance of the object is disfavored), i.e. the so called Ancient PWN scenario (*O. C. de Jager et al. (including O.Tibolla) arXiv:0906.2644*) <u>Ancient PWNe</u> are indeed a recent idea that could explain a large fraction of the TeV unidentified sources.

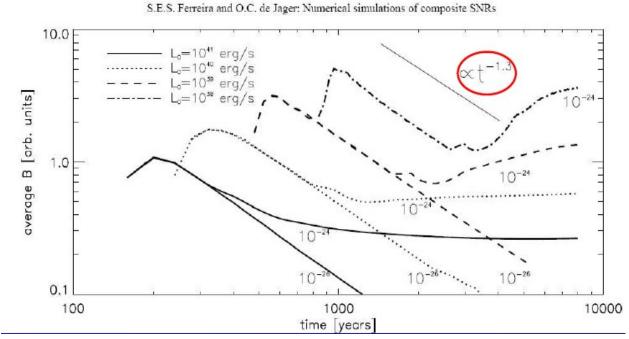

- The absence of counterparts (if confirmed), especially in X-rays, would suggest an <u>hadronic scenario</u>. However hadronic scenarios appears disfavored, unless we would place HESS J1507-622 at a very small distance, since the density of target material off the plane is low (e.g. SN 1006).

As mentioned, the difference in model leads also to a difference in the distance: a leptonic PWN scenario would place this source due to its quite small extension to a distance of several kpc (at least > 6 kpc; e.g Geminga) whereas a hadronic scenario would preferentially locate this object at distances of < 1 kpc where the density of target material is higher.

Omar Tibolla

In a scenario where the magnetic field decays as a function of time, the synchrotron emission will also fade as the PWN evolves. And the B-field is indeed expected to decay as a function of time and the power-law index of the decay of the average nebular field strength has been calculated by means of MHD simulations (Ferreira & de Jager, 2008)

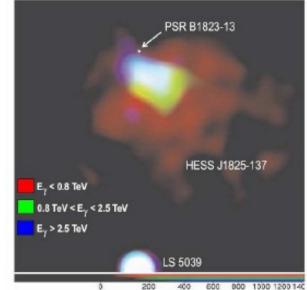

While the synchrotron emission is fading as the PWN evolves, the VHE emission depends on the CMB radiation field, which is constant on timescales relevant for PWN evolution.

For timescales shorter than the inverse-Compton lifetime of the electrons $(t_{IC} \approx 1.2 \times 10^{6} (Ee/1 \text{ TeV})^{-1} \text{ years})$, this will result in an accumulation of VHE electrons which will also lead to an increased gamma-ray production due to up-scattering of CMB photons.

Such accumulation of very-high energy electrons in a PWN has indeed been seen in several VHE PWNe (such as the source HESS J1825-137)

This idea seems supported by the fact that the VHE PWNe sizes generally increase with pulsar age while the X-ray PWNe sizes show the opposite trend.

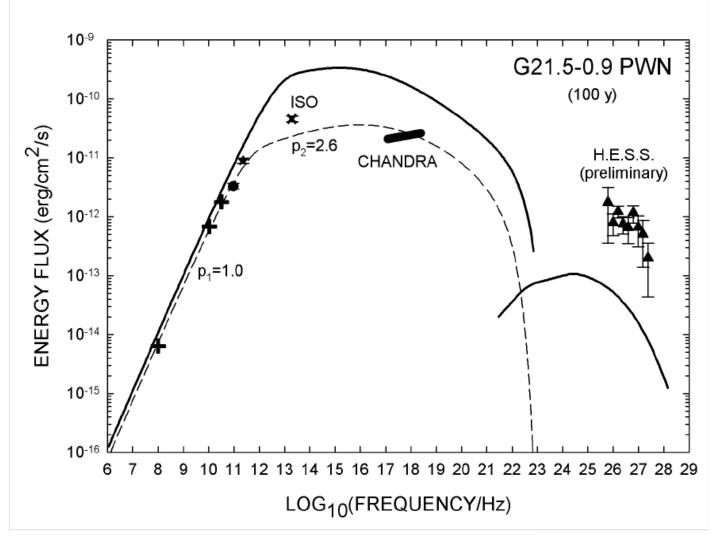

Moreover, for pulsars older than $\sim 10^3$ years the VHE PWNe are typically 100–1000 times larger than the sizes of the X-ray PWNe, while the difference is only a factor 2 for some younger PWNe, like the Crab Nebula (e.g. Kargaltsev & Pavlov 2010).

To summarize, during their evolution PWN may appear as gamma-ray sources with only very faint low-energy counterparts and this may represent a viable model for many unidentified TeV sources.

This effect can be clearly seen in the following example shown by Okkie de Jager in 2008.

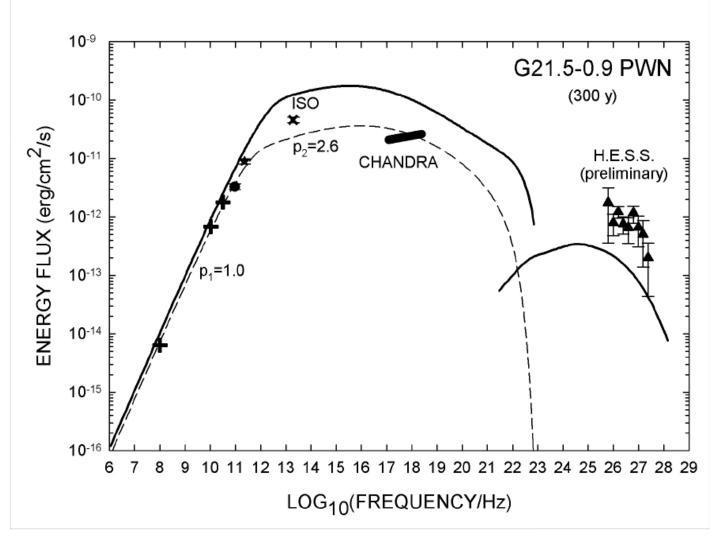

Example: G21.5-0.9 in the first 25 kyrs (100 y)

HESS J1507-622 (25 kyrs)

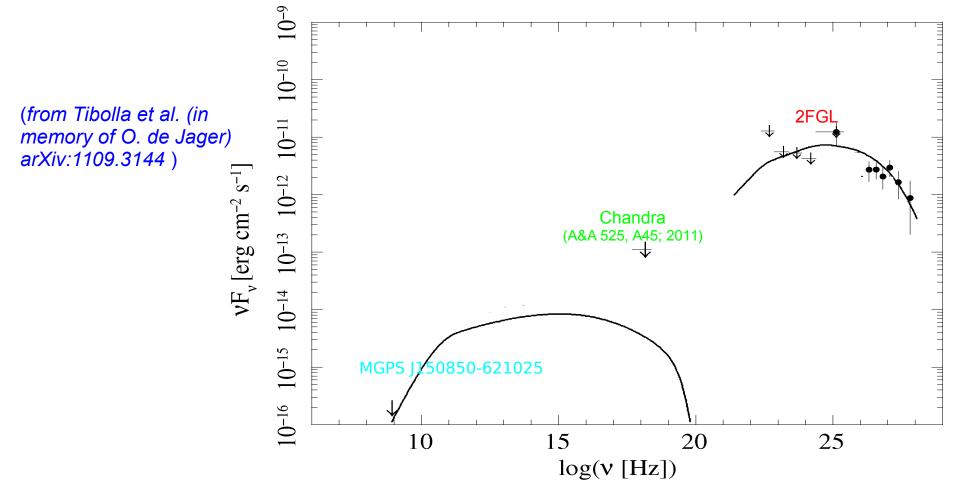

HESS J1507-622 does not have any SNR as possible counterpart and does not show any Pulsar close-by or coincident.

This is expected (PSR already spun-down, and X-ray nebula faded away below the sensitivity of current X-ray instruments), however it request a choice of the initial conditions for modeling (e.g. G21.5-0.9/PSR J1833-1034).

HESS J1507-622 (>50 kyrs)

We were having (A&A, 525, A45) constrains about the distance, now we have about the age...

Omar Tibolla

Tuxtla Gutierrez 27th of October 2016

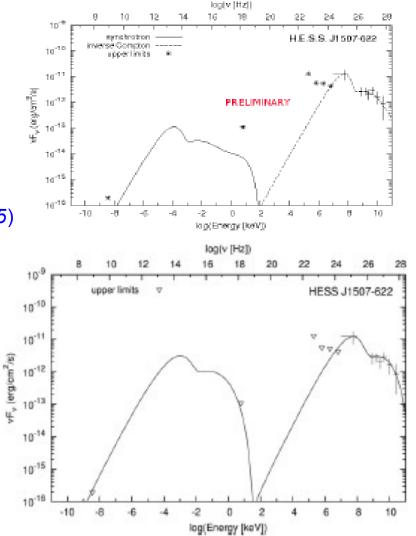

More "evolved" models

I showed here the basic idea, however, using much more stringent models (such as a "leaky box" and our new time dependent PWN model) we obtain comparable results.

Another corollarium: Starburst Galaxies

Another important consequence of these long-living γ -ray sources regards starburst galaxies: in fact it has been recently shown (Mannheim, Elsaesser and Tibolla 2012, Astroparticle Physics, 35, pp. 797-800) that PWNe are important and not negligible in explaining the TeV emission detected from NGC 253 and from M82.

PWNe associated with core-collapse supernovae in SFRs can readily explain the observed high TeV luminosities. The proof of this could arrive from deeper gamma-ray observations on other galaxies

According to me, we learn a couple of things:

1- Ancient PWNe seems a very natural way to explain unidentified high energy sources.

And the ancient PWN models seem to be able to explain most of these unidentified sources (e.g. Tibolla et al. 2013, arXiv:1306.6833).

2- If indeed at the termination shock of the Pulsar Wind also hadrons could be accelerated as well as leptons, not only PWNe but also unidentified sources (i.e. the dominant population at HE and VHE) can help in solving the CRs riddle.

3- Please note that, since in general PWNe Total Energy is comparable with SNRs Total Energy (or, at least, we can easily reach ~10% of it), IF hadrons can really be accelerated at the termination shock of Pulsar wind, this could indeed help the global picture of CR origin.

- Introduction to Cosmic Rays and "standard picture" of their origin.

- Detection techniques (GeV-TeV)
- What are Galactic unidentified sources?

Examples, "let's go to unids zoo": - HESS J1507-622 + ancient PWN - HESS J1741-302

(+~100 backup slides)

- 1- no real conclusions (in fact we are here at the Contested Astrophysics conference) => The question about the Origin of CRs is more open than ever
- 2- Additional CRs sources or much different models/scenarios seems to be required (in order to supply the missing CR fraction).
- 3- ONLY deep MWL studies can help.
- 4- regarding Unidentified Sources, they could really help, under the hypothesis of hadron acceleration at the pulsar wind termination shock.

Announcement (master students): HEA course

If you are interested in deepening your knowledge in <u>HIGH ENERGY</u> <u>ASTROPHYSICS</u>, we have an open course dedicated to master students (maestria) of FCFM master program.

Please check MCTP web-page, for more details:

http://mctp.mx/cursos-a-largo-plazo.html

Dr. Omar Tibolla: Long term courses High Energy Astrophysics

Dr. Omar Tibolla

Summary of High Energy Astrophysics Course.

It basically consists of an introduction to Cosmology, Particle Physics and Astrophysics; and after we go to more specific topics of Astropatricle Physics (including "Atmospheric Physics"!) and Gamma-ray Astronomy. The lectures so far are structured in the following way:

- 1. Introduction
- 2. Universe Composition + Density and Temperature Evolution
- 3. Cosmic Microwave Background (CMB)
- 4. Dark Energy, Nucleosynthesis and Radiation Era
- 5. Decoupling, Neutrino Sources
- and Solar Neutrinos
- 7. Solar Neutrinos Results, Stellar Evolution, Supernovae
- 8. Cosmic Rays
- 9. Atmosphere
- 10. Particles and Radiation in Matter
- 11. Bremsstrahlung and Hadronic Interactions
- 12. Cherenkov Radiation and E.M. Showers
- 13. CR Spectrum and Cosmic Accelerators
- 14. UHECR: Ultra High Energy Cosmic Rays
- 15. Underground Cosmic Rays (e.g MACRO, EASTOP and applications)
- 16. Supernova Neutrinos & Neutrino Astronomy
- 17. Neutrino Oscillations & Atmospheric Neutrinos
- 18. Magnetic Monopoles
- 19. Discovery of Gamma-rays from space and GRBs
- 20. Gamma-ray astronomy history and introduction
- 21. Gamma-ray astronomy: SNRs
- 22. Short introduction to Active Galactic Nuclei and to AGN "standard" model
- 23. Unidentified Sources Intro

Tuxtla Gutierrez 27th of October 2016

Announcement (ALL students): many thesis opportunities

Notes/opportunity for students interested in their bachelor, master or Ph.D. thesis on related topics:

- The Mexican community is realizing the importance of investigating the riddle of Cosmic Ray origin (e.g. I just got approved a Conacyt project on related topics).

- MCTP is new born and rapidly expanding (e.g. MCTP just became a category 2 UNESCO institute), as well as its High Energy Astrophysics group (e.g. recently we hired another full professor, Prof. Dr. Sarah Kaufmann, expert in high-energy multi-wavelength astronomy, last week seminario).

- The relationships between FCFM and MCTP are extremely close (e.g. in High-Energy Astrophysics we work as a unique research group).

Some UNACH students already finalized or started their thesis with our group on subjects that are very closely related to topics discussed in my talk: e.g.
Laila Vleeschower Calas, bachelor thesis on IGR J18490-0000 (supervised by C. Alvarez; co-supervised by S. Kaufmann and O. Tibolla).
Juan Carlos Espinosa, master thesis on HESS J1841-055 (supervised by O. Tibolla; co-supervised by S. Kaufmann and C. Alvarez).

So, if interested, don't hesitate to contact us! Omar Tibolla
